

# Space Weather and The PROGRESS project idea and concept

[ssg.group.shef.ac.uk/progress/html](http://ssg.group.shef.ac.uk/progress/html)

This project has received funding from the *European Union's Horizon 2020 research and innovation programme* under grant agreement No 637302.

# Space Weather

“Just as weather can be expressed as a set of atmospheric parameters that are important not only for our comfort but also determine conditions for the operation of technological systems on the ground and in the atmosphere, **space weather** is expressed by the set parameters relating to the near Earth environment that determine important conditions for many modern technological systems operating on the terrestrial surface (e.g. power grids), in the atmosphere (aviation) and in the space (satellites, manned missions).”

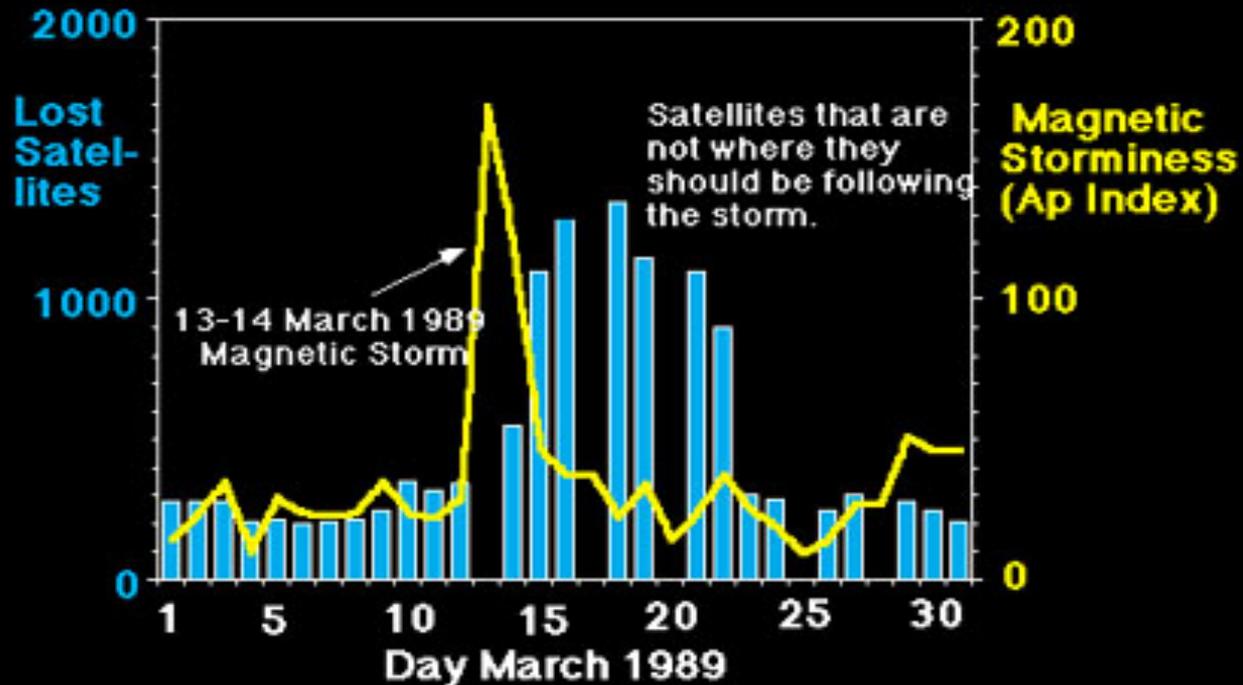

From the application to PROGRESS project that is coordinated by the University of Sheffield.

# Space weather effects

1. Geomagnetically Induced Current (Power Grids, Pipelines etc)
2. Radiation effects on modern technological systems and human health
3. Satellite locations
4. Communication (propagation radio waves), in particular Solar Flare Radio Blackouts
5. Navigation Space debris

# Effects of Space Weather Atmospheric Drag

Satellite Tracking Problems  
After March 13-14, 1989 Storm

Increased activity heats up the atmosphere

scale-height increases

drag increases

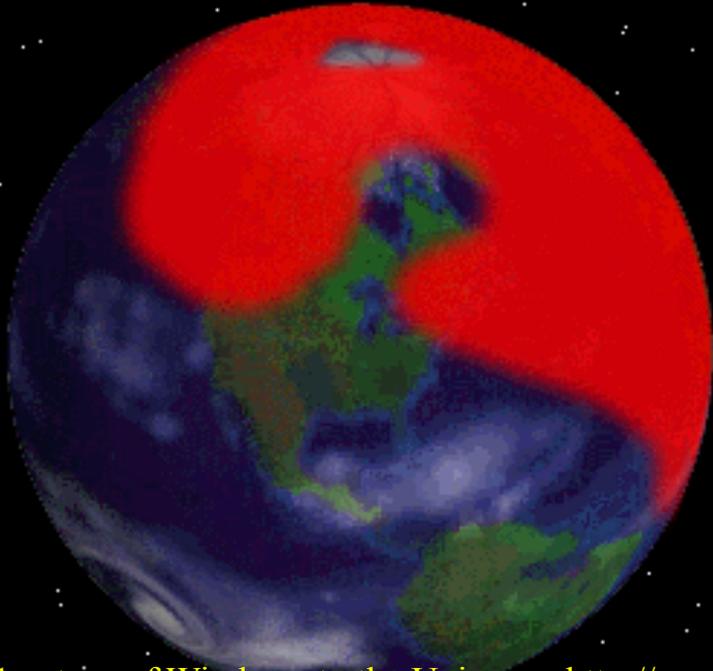

Debris and low-altitude spacecraft fall into atmosphere

Deorbiting of the MIR station to the Pacific Ocean in March 2001

”good” space weather

slowed down the natural orbital decay and the process took longer than expected

# Effects of Magnetic storms Atmospheric Drag

Courtesy of Windows to the Universe, <http://www.windows.ucar.edu>

Satellites at LEO experience friction due to atmosphere.

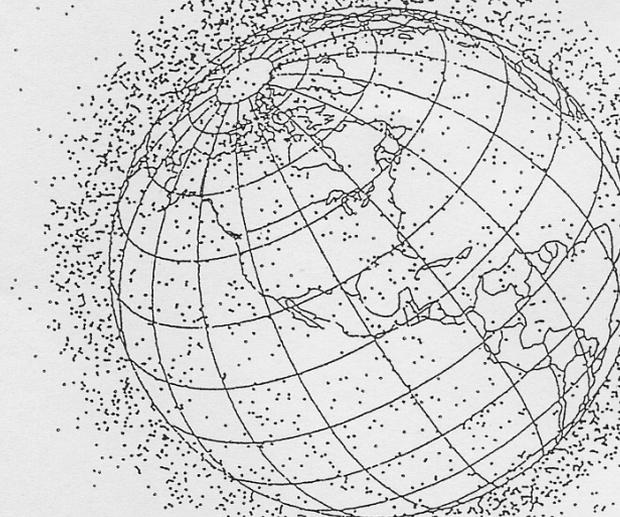

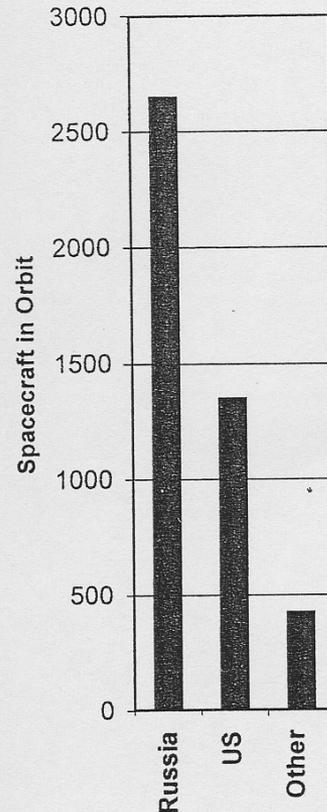

During geomagnetic disturbances electric currents increase heating and contribute to the expansion of atmosphere.

“During medium storms density of upper atmosphere increases up to 20%. The figure above illustrates such an increase. Red colour indicated area where density increase  $>20\%$ . During strong storms density increase can be as high as 100%. “ Windows to the Universe”

Therefore strong geomagnetic storm require re-locate the spacecraft position.

# Drag and space debris

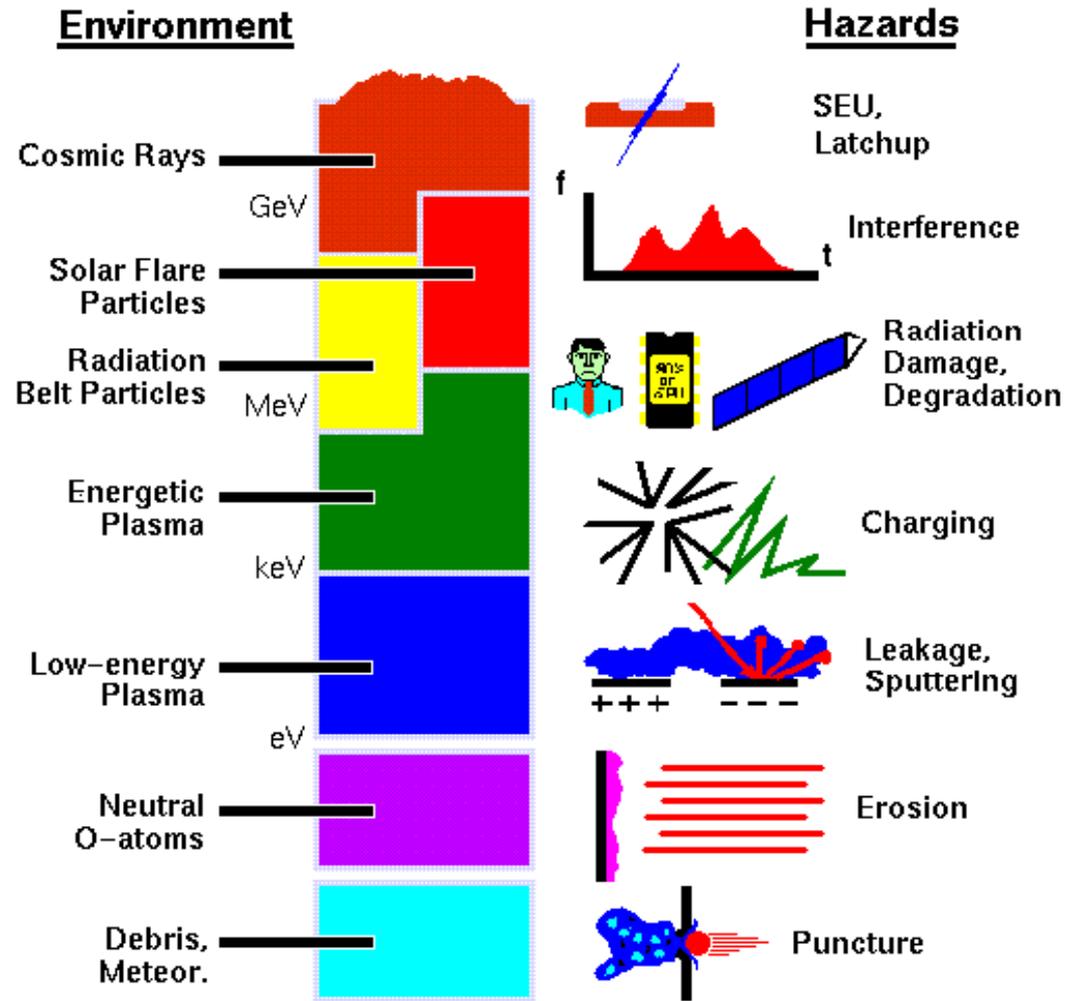

- amount of debris in space grows
  - > 10 cm bodies: > 9000
  - Hundreds of thousands smaller pieces

**1957-2001 4400  
successful  
spacecraft  
launches.

## AURORAL PHENOMENA.

### Remarkable Effect of the Aurora Upon the Telegraph Wires.

The Aurora which occurred on Thursday night produced effects much more remarkable than those of the previous Sunday night. The auroral currents were sufficiently powerful on Thursday to enable the telegraphic operators at Portland to transmit messages to Boston without resorting to the use of the batteries; and similar phenomena were observed at Pittsburgh. A series of experiments upon this curious electrical condition was instituted at the Boston office. The results are noticed in the Boston papers, which publish the following statements from the operators:

TELEGRAPH OFFICE, No. 31 State-street, }  
Boston, Friday, Sept. 2, 1859. }

The same night the following conversation took place between the operators at the Boston and Portland offices:

*Boston* (to *Portland* operator)—'Please cut off your battery entirely from the line for fifteen minutes.'

*Portland*—'Will do so. It is now disconnected.'

*Boston*—'Mine is also disconnected, and we are working with the auroral current. How do you receive my writing?'

*Portland*—'Better than with our batteries on. Current comes and goes gradually.'

232	N24	5/18	East limb passage of one of the greatest activity complexes of Solar Cycle 20. Composed of three overlapped spot groups at time of first appearance, two of which were growing.
		5/20	Birth of fourth spot group on southern border of complex. Westward relative motion of this group, with respect to large spots to the north, may have contributed to conditions for great flare of 21 May in center of complex.
		5/21	"Collision" between central and western members of the complex, as growth and expansion of central member moved its leader spot into the follower plage of the western member. Large flare occurred over the neutral line between the groups.
		5/23	"Collision" and merger of leader of easternmost member with follower of central member, creating large "delta" magnetic configuration. Closest separation between the opposite-polarity spots coincided with great white-light, proton flare at 1840 UT (see <i>UAG Report 5</i> ). These spots moved in a rotary pattern with respect to one another during 21-26 May.
a		5/28	Additional great flare over the "delta" configuration.

**Table 1.** The 25–27 May 1967 Geomagnetic, Ionospheric, and Atmospheric Effects at 1 AU

Effect	Measurement	References
Ground magnetic and ionosphere severe storm	$Kp = 9$ for 6 h = NOAA G5 class, $Kp \geq 7$ – for 27 continuous hours, top 25 $Aa_m^*$ storm; $Aa_m^* = 274$	NASA OMNIweb [Findlay et al., 1969; Cliver and Svalgaard, 2004]
Extreme ionospheric storm 25–26 May severe positive-negative phases	100% TEC increase on 25 May due to geomagnetic storm followed by most dominant negative phase in TEC ever recorded	Webb [1969], Low and Roelofs [1973], and Mendillo [2006]
Significant auroral precipitation effects	Scintillation on satellite beacon signal—signal lost early 25 May	Goodman [1968]
Hot ionosphere at 1000 km	Electron temperature > 6500 K, extraordinary structuring in electron density and temperature in auroral zone observed by Explorer 22 satellite	Findlay et al. [1969]
Aurora at low latitudes 25–26 May	New Mexico 32° north geographic, Alabama; overhead in Washington DC Class II aurora in Devon, UK; off-scale intensity;	Castelli et al. [1968], Findlay et al. [1969, Figure 1], and Smith and Webber [1968, Table 1]
Significant keV auroral proton precipitation 25–26 May	> 35 mW/m <sup>2</sup> during polar pass of satellite OV1-10; 114 kR of emission	Metzger and Clark [1971]
Heated thermosphere satellite drag	400 K temperature spike after 6 h, LOGACS apogee decreases by 100 km	Jacchia [1969] and DeVries [1972]
Geomagnetic micropulsations	“Spasmodic” pulsations of 40 mV/km at 10–20 mHz	Smith and Webber [1968]
Coherent global oscillations in VLF emissions	Simultaneous global oscillations at 5–8 kHz, U.S., Europe, and Japan	Harang [1968a, 1969]
Plasmapause greatly distorted	Plasmasphere eroded to $\sim L = 2$ complex filamentary structure	Hayakawa et al. [1975] and Grebowsky et al. [1974]
Dst superstorm, eighth largest 25–26 May	Sudden commencement +55 nT, Dst = –387 nT; mean $Dst_{MP} = -230$ nT, very asymmetric ring current	Kyoto Dst record [Balan et al., 2016; Akasofu et al., 1969]
Magnetospheric compressions 25–30 May	Sudden Storm Commencements (SSCs) near-equatorial $\Delta H$ of 737 nT	Lindgren [1968, Figures 6 and 9 and Table IV]
Structuring of solar energetic particle fluxes	Energetic proton enhancements ahead of and at SSC’s 24–31 May, IMP 1 and IMP 4	Lindgren [1968, Figure 4], Bostrom et al. [1969], and Lanzerotti [1969a, 1969b]
Magnetopause inside GEO orbit on May 25	> 3 h; 2039–2354 UT ATS 1 geostationary satellite	Russell [1976] and Coleman [1970]
Semipermanent disturbances in electron and proton radiation belts at $L < 3.5$	Factor of 100 increase in 0.28 MeV electrons at $L = 2.2$ , increase of 0.265 MeV protons between $L = 2.25$ and 3.25 on 25 May	Bostrom et al. [1970], Rothwell and Katz [1973], and Tomblin and Kreplin [1970]
Stepped Forbush cosmic ray decrease	11% at Deep River Observatory, Marked north-south asymmetry, Cosmic ray steaming direction reversed 25–31 May	Harang [1968b], Akasofu et al. [1969, Figure 8], and Lindgren [1968]

Table From : Knipp, D. J., et al. (2016), Space Weather, 14, doi: 10.1002/2016SW001423

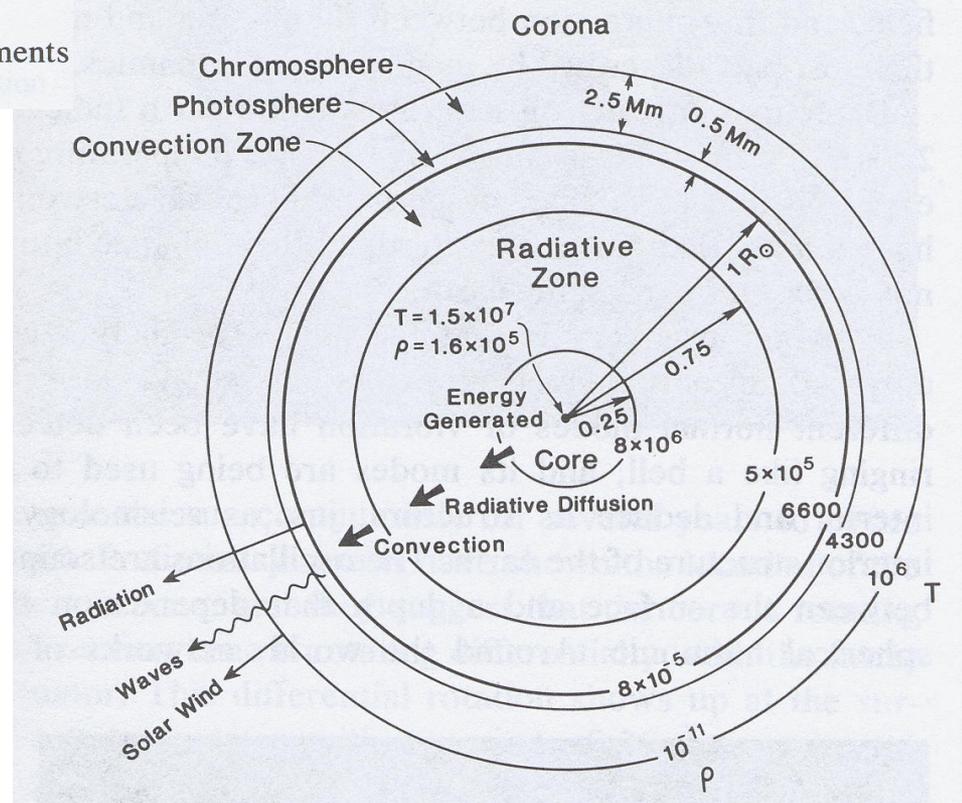

“Cold War military commanders viewed full scale jamming of surveillance sensors as a potential act of war” ( Knipp, D. J., et al. (2016), Space Weather, 14, doi: 10.1002/2016SW001423)

**Figure 7.** Number of active duty AWS Space Environment Support Positions. These numbers are taken from historical reports and rosters as well as the online AWS history. Values have an uncertainty of about 20% given that military members were often reassigned on short notice and some performed both SESS and non-SESS duties.

# Sun

Age =  $4.5 \times 10^9$  yr  
 Mass =  $1.99 \times 10^{30}$  kg

# Objectives

1. Develop a European numerical MHD based model that will enable the advanced forecast of solar wind parameters at L1.
2. Use system science methodologies alongside those currently available (empirical, ANN) to forecast the evolution of geomagnetic indices in response to the solar wind.
3. Construct a new set of statistical wave models to describe the plasma wave environment of the inner magnetosphere that will accurately reflect the physics of the dynamics of the radiation belts under the influence of the solar wind.

## Objectives

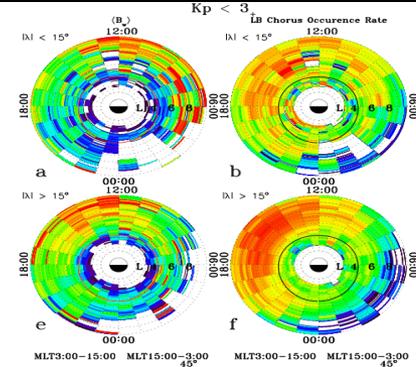

4. Incorporate forecasting capabilities into the physics based numerical model for low energy electrons IMPTAM that currently is able to provide a now-cast only.
5. Develop a novel, reliable, and accurate forecast of the radiation environment in the region of radiation belts exploiting the fusion between data based models for high energy fluxes at geostationary orbit SNB<sup>3</sup>GEO, IMPTAM, the most advanced model for high energy electrons in the radiation belts – VERB, and state of the art data assimilation methodology.
6. To combine the prediction tools for geomagnetic indices and radiation environment within the magnetosphere with the forecast of solar wind parameters at L1 and upstream of the magnetosphere to significantly increase the advance time of the forecast.

# Overview

**Solar wind propagation from Sun to L1 (AWSO-M/SWIFT)**

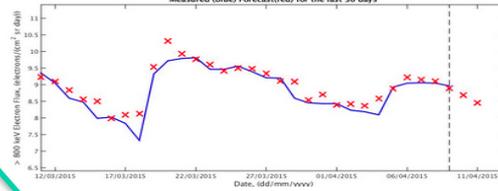

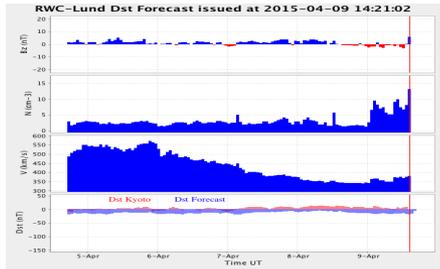

**Development of new statistical models**

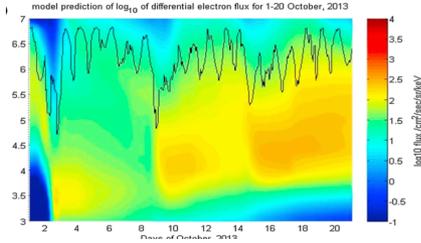

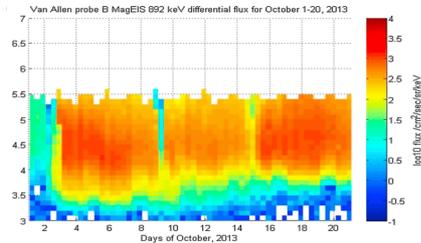

**Low energy electron model**

## Relativistic Electron Forecast Model

Presented by the USAF and NOAA/ [Space Weather Prediction Center](#)

The impact of high-energy (relativistic) electrons on orbiting satellites can cause electric discharges across internal satellite components, which in turn leads to spacecraft upsets and/or complete satellite failures. The Relativistic Electron Forecast Model predicts the occurrence of these electrons in geosynchronous orbit.

Plots and data are updated daily at 0010 UT. Dashed vertical lines indicate the last vertical value. When the input parameters are not available, the forecast is not shown.
